Report subject experiments. Proteins used were
glycinin from Glycine hispida Max, legumin from
Pisum sativum L. and edectin from Cannabis sativa L.
Proteins were restored by nascent hydrogen. Method
of investigation was anaphylaxis of guinea pigs. Re-
sults show that restored proteins lost their immuno-
biological activity to a considerable extent. Sub-
mitted 27 Jan 1948.

EXCERPTA MEDICA Sec.4 Vol.11/4 Med.Microb. etc. April 1958

804. SOME DERIVATIVES OF GRAMICIDIN C(Russian text) - Znamenskaya
M. P. and Belozerskii N. A.N. Bach Biochem. Inst. of the USSR
Acad. of Sci., Moscow - ANTIBIOT. 1957, 1 (36-40) Illus. 3

The activity of gramicidin depends on the presence in its molecule of a free amino-group. The influence of introduction into the amino-group of various alkyl radicals on the activity of the preparation was studied. Methyl, ethyl, propyl and amyl radicals introduced into the amino-group had no obvious influence on the anti-bacterial action of the preparation against *M. pyogenes aureus*. Benzylated gramicidin had no antibiotic properties. Substitution of a guanidine group for the amino-group did not influence the activity of the preparation against *M. pyogenes aureus*. There was also no change following nitration of the preparation. Gramicidin deaminated before nitration did not show any activity.

TITLE: Self-Oxidation of Reserve Proteins Enriched With Hydrogen
(O samookislenii zapasnykh belkov, obogashchennykh vodorodom)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 120, Nr 5, pp.577-580
(USSR)

ABSTRACT: In previous investigations of the first mentioned author it was proved that the reserve proteins of the seeds themselves can serve as reducing agents for oxidizing substances as KJ_0_3 , $K_3Fe(CN)_6$, J_2 and others, if they are enriched with hydrogen by reduction (Ref 1). The second author proved the same for 2 - 6 dichlorophenol - indophenol and methylene blue (Table 1). It was interesting to determine the magnitude of the reducing effect of such proteins with respect to oxygen, as in the living cell protein substances can occur in to a varying degree reduced state in different stages of development of the cells and therefore can participate in the respiration of the cell because of a binding with atmospheric oxygen. As in earlier investigations the authors used reserve proteins: glycinin from soja beans, legumin from peas and edestin from hemp seeds (produced according to Osborn).

Card 1/3

Self-Oxidation of Reserve Proteins Enriched With Hydrogen 30V/20-120-3-39/67

They showed a different degree of reduction and were stored for different periods. A storing in an air-dried state reduced the reduction power of legumin, which apparently was gradually oxidized by atmospheric oxygen. Table 2 shows results of the experiments dealing with the oxidation velocity of glycinin. The authors are of opinion that the oxidation by $K_3Fe(CN)_6$ is accompanied by the same effects of atmospheric oxygen, which fact is proved by Table 3. The movable oxygen of organic substances (H-oxidized alkaline form) has the same effect. The possibility of the formation of peroxides can be assumed as explanation (Ref 3). The conducted experiments proved this assumption. Tables 4 and 5 show, however, that glycin and edestin consume smaller quantities of H_2O_2 than the initial proteins, when they are reduced. This phenomenon has hitherto not been cleared up. Nevertheless it is possible to draw the conclusion that the reserve proteins of the seeds enriched with oxygen can take part in several metabolic processes in the cell, among them in respiration, by means of binding the free oxygen. There are 5 tables and 6 references, 6 of which are Soviet.

TITLE:

The Influence Produced by Oxygen Upon the Desoxyribonucleic Acid of Actinomyces Mycelium (Vliyaniye kisloroda na dezoksi-ribonukleinovyyu kislotu mitseliya aktinomitseta)

PERIODICAL:

Doklady Akademii Nauk SSSR, 1957, Vol. 114, Nr 4,
pp. 856-858 (USSR)

ABSTRACT:

In their previous publication the authors showed that the influence of some oxidizing agents (red blood salt, hydrogen peroxide) considerably lowers the intensity of the color reaction (Diché) on the desoxyribonucleic acid (henceforth called DNA). This is true for objects of different origin, especially for the mycelium of Actinomyces. The authors found that this fact, in an analogous ratio was completely missing in a freshly prepared struma gland preparation as well as in a DNA preparation isolated from it, which latter served as a comparison standard. At that time they expressed the opinion that the different behaviour of DNA of different origin, namely of its carbon hydrate part, with regard to oxidation is determined not only by its structural peculiarities but also by the total specific qualities of the substances

Card 1/4

The Influence Produced by Oxygen Upon the Desoxyribonucleic Acid of Actinomyces Mycelium 20-114-4-48/63

connected with it. In other words, the different stability of the DNA reflects more or less the physiological peculiarity of that object or tissue in which it occurs. In this connection it was interesting to determine whether the oxidizing agents would also influence the intensity of Dicé's reaction, if DNA had been liberated from the actinomycetes (pl.). The nucleic acids isolated from Actinomyces globisporus streptomycini possess a number of peculiar properties: this DNA, unlike such from animal tissues, may be extracted easily from mycelium. Therefore it is apparently less aggregated and lower molecular than the latter ones. It further represents a mixture or a combination of ribonucleic- and desoxyribonucleic acid. The experiments showed that after a 40 hours' influence of a 0,15% hydrogen peroxide solution the intensity of Dicé's reaction remained the same. That was also the case in the DNA of struma gland preparations. Thus the problem was raised where to find the actual cause for the decrease in the intensity of Dicé's reaction in Actinomyces mycelium, which had been subjected to oxidation. It might have been possible that the Dicé's reaction carried through on mycelium had directly lessened the intensity of this reaction, because of

Card 2/4

The Influence Produced by Oxygen Upon the Desoxyribonucleic Acid of Actinomyces Mycelium 20-114-4-48/63

of partial desaggregation of the desoxyribonucleoproteides with their subsequent washing out of the decomposed mycelium. In order to clarify this problem the authors studied more closely the influence of oxygen upon DNA in Actinomyces mycelium. As a standard they used a DNA-preparation from the struma gland with a certain content of phosphorus. Influence of oxygen upon a mycelium suspension in water caused a decrease in the content of DNA by 50-70% of the original amount, as compared with only 2% in fresh mycelium. Another oxygen blast did not change the intensity of the Dicher's reaction. DNA must apparently exist in two forms in mycelium, one of them being more mobile and capable of reaction than the other which is not altered by oxygen. The authors maintain that the decrease in intensity of Dicher's reaction occurs because of oxidizing-reducing processes, which no doubt take place under participation of the fermentative system of the mycelium, for in boiled mycelium it does not occur. In this connection the authors maintain that the same decrease under the influence of red blood salt or hydrogen peroxide did not only occur because of an actual oxidation of the DNA, but

Card 3/4

The Influence Produced by Oxygen Upon the Desoxyribonucleic Acid of Actinomyces Mycelium 20-114-4-48/63

also due to the intensification of the desaggregation process of the desoxyribonucleoproteides which followed their liberation from the mycelium.

TITLE: Use of the principles of the wave movement of alluvium in calculating channel deformations

SOURCE: Leningrad. Gosudarstvennyy gidrologicheskiy institut. Trudy, no. 120, 1965.
Issledovaniya ruslovykh protsessov, 3-24TOPIC TAGS: hydrology, wave propagation, flow rate, alluvium, SURFACE WATER,
Soil mechanics

ABSTRACT: The author proposes a method of calculating deformations on the basis of the change of channel forms. The author distinguishes microforms (small ridges) from mesoforms (larger channel formations). Microforms are more mobile than mesoforms. Mesoforms require more time for their rearrangement. Although there are differences between micro- and mesoforms they are both a wave form of sediment transportation and therefore the principles that have been established for microforms can be applied to mesoforms. In this article the author dwells on the unified system of microforms, developed at GGI which encompasses the entire diversity of microforms and is related with criteria common to the

Card 1/2

L 389584.6

ACC NR: AT6016516

entire field of sediment transportation. Generalized empirical characteristic curves of sand waves are given. From these curves it is possible to determine the relationship between the average hydraulic characteristics of the stream and the characteristics of the sand waves formed on its bottom. The calculation, which in essence is an experimental forecast of channel deformations, yields a satisfactory agreement with actual deformations in a channel and can be used to estimate deformations in rather straight channels. The structural approach to estimating deformations has an advantage over other methods in that it permits estimating the actual change of forms. This method can be used, for example, when solving problems of the clogging of collector wells and other structures by large sandy accumulations of sediments. When laying pipelines under a river bottom it is necessary to determine their depth of laying so as to ensure normal operation and prevent erosion. The depth of laying the pipes can be determined if the thickness of the active layer of the sediments is taken into account. This thickness is determined by the height of the waves moving in the channel and will change in relation to the flow rate. By using the proposed method it is possible to estimate the range of change of this quantity for design purposes. The proposed method can also be used when estimating the stability of bars and determining minimal depths since reformation of a river bottom has a definite effect on shipping conditions. The proposed method pertains to an estimate of deep deformations, however it can be used to solve more complex problems when combined with a morphological analysis. Orig. art. has: 6 tables, 9 figures, and 2 formulas.

TITLE: Geomorphological Districts and Relief Types Near
Leningrad (Geomorfologicheskiye rayony i tipy rel'-
yefa okrestnostey g. Leningrada)

PERIODICAL: Vestn. Leningr. un-ta, 1956, Nr 24, pp 152-162

ABSTRACT: The history and relief features of the territory
around Leningrad make it possible to divide the
region into three geomorphological districts: 1) the
Silurian plateau, a region where erosion is intensive
and where Quaternary deposits and accumulative glacial
formations are thin; 2) the Neva plain, a region
characterized by abrasion-accumulation activity in
late glacial and post-glacial basins; 3) the Karelian
isthmus, a region of glacial and water-glacial accumu-
lation with a subsequent abrasion in late glacial and
post-glacial basins. The types of relief are shown

Card 1/2

Geomorphological Districts (Cont.)

Znamenskaya, Leningrad Order of the Red Banner of Labor Scientific Research Institute of Blood Transfusion (director, Docent A. D. Belyakov; scientific director, Prof A. N. Filatov, Corresponding Member, Academy of Medical Sciences USSR), Problemy Gematologii i Perelivaniya Krovi, Vol 2, No 2, Mar/Apr 57, pp 41-46

The qualitative amino-acid composition of protein hydrolysates recommended by the Leningrad Institute of Blood Transfusion for parenteral feeding of patients was studied by means of paper chromatography. The solution thus analyzed was subjected to iontophoresis in a three-chamber apparatus, for subsequent separation into three fractions: alkaline (diamino acids), neutral (monocamino acids), and acid (dicarboxylic amino acids). Each fraction was analyzed by means of chromatograms. It was found that the protein hydrolysates L-103, aminokrovin, aminol, aminorastin, etc., are identical qualitatively and contain all the essential amino acids. (U)

Title : The Microchemical Determination of Nickel
in Hydrogenated Fats

Orig Pub: Tr. Krasnodarsk. in-ta pishch. prom-sti, 1955,
No 11, 47-49

Abstract: A micromethod for the determination of nickel
in hydrogenated fats and margarine is described.
A 1 gm sample of the fat is melted in a
crucible and ignited; when the ignition is
complete the residue is rosted in a muffle furnace
which has been heated to a dull red heat. The
residue in the crucible is dissolved in a few
drops of aqua regia and the solution evaporated

TITLE:	<u>Deformation properties of polymeric materials</u>		
SOURCE:	Ref. zh. Khimiya, Part II, Abs. 7S621		
REF SOURCE:	Tr. N.-i. proyektno-konstrukt. in-ta tekhnol. mashinostr., no. 1, 1965, 75-95		
TOPIC TAGS:	thermosetting material, thermoplastic material, polymer rheology, thermoelasticity, elastic modulus, thermal expansion		
ABSTRACT:	<p><u>Thermosetting</u> and <u>thermoplastic</u> polymers in the range of small deformations were tested, and their <u>physicomechanical</u> characteristics were treated mathematically. The following quantities were determined: thermal extension of polyolefins, dependence of Brinell hardness on the elastic modulus and molecular weight, initial elastic modulus from the thermoelastic effect, and relationship between the latter and the coefficient of linear thermal expansion. The elastic properties of PVA fibers were studied at ~20°. On the basis of the experimental data, a nomogram of the thermoelastic properties of thermoplastic polymers was constructed which enables one to find the relationship between the initial <u>elastic modulus</u>, the coefficient of linear thermal expansion, and the thermoelastic coefficient.
